Como Entregar esse projeto?

- 1.Crie um novo repositório no github com um nome a sua preferência
- 2.Crie um modelo de previsão com seus devidos pontos de extremidade configurados
- 3.Escreva o passo a passo desse processo em um readme.md de como você chegou nessa etapa
- 4. Salve nesse repositório o readme.md e o arquivo .json de pontos de extremidade
- 5.Compartilhe conosco o link desse repositório através do botão 'entregar projeto'
- 6.Passo-a-Passo https://microsoftlearning.github.io/mslearn-ai-fundamentals/lnstructions/Labs/01-machine-learning.html https://microsoftlearning.github.io/mslearn-ai-fundamentals/lnstructions/Labs/02-content-safety.html

No passo "URL da Web", informei a URL https://aka.ms/bike-rentals do conjunto de dados.

Todas as vezes que tentei com a url fornecida acima deu erro e tive de reiniciar, então achei nesse git https://github.com/casjunior93/Projeto-DIO---Trabalhando-com-Machine-Learning-na-Pratica-no-Azure-ML/blob/main/README.md uma url alternativa, usei essa URL: https://raw.githubusercontent.com/MicrosoftLearning/mslearn-ai-fundamentals/main/data/ml/daily-bike-share.csv e continuei seguindo as instruções da url: https://microsoftlearning.github.io/mslearn-ai-fundamentals/lnstructions/Labs/01-machine-learning.html

```
teste.json
```

```

Resultado:

{ "Results": [ 365.0545351117373 ] }
```

Sign into the Azure portal at https://portal.azure.com using your Microsoft credentials.

1.Select + Create a resource, search for Machine Learning, and create a new Azure Machine Learning resource with the following settings:

- •Subscription: Your Azure subscription.
- •Resource group: Create or select a resource group.
- •Name: Enter a unique name for your workspace.
- •Region: Select the closest geographical region.
- •Storage account: Note the default new storage account that will be created for your workspace.
- •**Key vault**: Note the default new key vault that will be created for your workspace.
- •Application insights: Note the default new application insights resource that will be created for your workspace.
- •Container registry: None (one will be created automatically the first time you deploy a model to a container).

2.Select **Review + create**, then select **Create**. Wait for your workspace to be created (it can take a few minutes), and then go to the deployed resource.

3.Select **Launch studio** (or open a new browser tab and navigate to https://ml.azure.com, and sign into Azure Machine Learning studio using your Microsoft account). Close any messages that are displayed.

4.In Azure Machine Learning studio, you should see your newly created workspace. If not, select **All workspaces** in the left-hand menu and then select the workspace you just created.

Use automated machine learning to train a model

Automated machine learning enables you to try multiple algorithms and parameters to train multiple models, and identify the best one for your data. In this exercise, you'll use a dataset of historical bicycle rental details to train a model that predicts the number of bicycle rentals that should be expected on a given day, based on seasonal and meteorological features.

Citation: The data used in this exercise is derived from Capital Bikeshare and is used in accordance with the published data license agreement.

1.In Azure Machine Learning studio, view the **Automated ML** page (under **Authoring**).

2.Create a new Automated ML job with the following settings, using **Next** as required to progress through the user interface:

Basic settings:

•lob name: mslearn-bike-automl

•New experiment name: mslearn-bike-rental

•Description: Automated machine learning for bike rental prediction

•Tags: none

Task type & data:

•Select task type: Regression

•Select dataset: Create a new dataset with the following settings:

•Data type:

•Name: bike-rentals

Description: Historic bike rental data

•Type: Tabular

•Data source:

Select From web files

•Web URL:

•Web URL: https://aka.ms/bike-rentals ---→Trocar pela url

alternativa:

https://raw.githubusercontent.com/MicrosoftLearning/mslear n-ai-fundamentals/main/data/ml/daily-bike-share.csv

•Skip data validation: do not select

•Settings:

•File format: Delimited•Delimiter: Comma•Encoding: UTF-8

•Column headers: Only first file has headers

•Skip rows: None

•Dataset contains multi-line data: do not select

·Schema:

•Include all columns other than Path

•Review the automatically detected types

Select **Create**. After the dataset is created, select the **bike-rentals** dataset to continue to submit the Automated ML job.

Task settings:

Task type: RegressionDataset: bike-rentals

Target column: Rentals (integer)Additional configuration settings:

•Primary metric: Normalized root mean squared error

•Explain best model: Unselected

•Use all supported models: <u>Un</u>selected. You'll restrict the job to try only a few specific algorithms.

•Allowed models: Select only RandomForest and LightGBM — normally you'd want to try as many as possible, but each model added increases the time it takes to run the job.

•Limits: Expand this section

•Max trials: 3

•Max concurrent trials: 3

•Max nodes: 3

•Metric score threshold: 0.085 (so that if a model achieves a normalized root mean squared error metric score of 0.085 or less, the job ends.)

•**Timeout**: 15

•Iteration timeout: 15

•Enable early termination: Selected

•Validation and test:

Validation type: Train-validation splitPercentage of validation data: 10

•Test dataset: None

Compute:

•Select compute type: Serverless

•Virtual machine type: CPU

·Virtual machine tier: Dedicated

•Virtual machine size: Standard_DS3_V2*

•Number of instances: 1

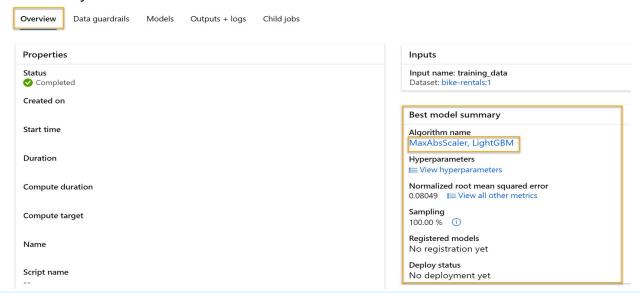

- * If your subscription restricts the VM sizes available to you, choose any available size.
- 3. Submit the training job. It starts automatically.
- 4. Wait for the job to finish. It might take a while now might be a good time for a coffee break!

Review the best model

When the automated machine learning job has completed, you can review the best model it trained.

1.On the **Overview** tab of the automated machine learning job, note the best model

2.summary.

Note You may see a message under the status "Warning: User specified exit score reached...". This is an expected message. Please continue to the next step.

- 3. Select the text under **Algorithm name** for the best model to view its details.
- 4. Select the **Metrics** tab and select the **residuals** and **predicted_true** charts if they are not already selected.

Review the charts which show the performance of the model.

The **residuals** chart shows the residuals (the differences between predicted

and actual values) as a histogram. The **predicted_true** chart compares the predicted values against the true values.

Deploy and test the model

1.On the **Model** tab for the best model trained by your automated machine learning job, select **Deploy** and use the **Web service** option to deploy the model with the following settings:

Name: predict-rentals

Description: Predict cycle rentals

•Compute type: Azure Container Instance

•Enable authentication: Selected

2. Wait for the deployment to start - this may take a few seconds. The **Deploy status** for the **predict-rentals** endpoint will be indicated in the main part of the page as Running.

3. Wait for the **Deploy status** to change to Succeeded. This may take 5-10 minutes.

Test the deployed service

Now you can test your deployed service.

1.In Azure Machine Learning studio, on the left hand menu, select **Endpoints** and open the **predict-rentals** real-time endpoint.

2.On the **predict-rentals** real-time endpoint page view the **Test** tab.

3.In the **Input data to test endpoint** pane, replace the template JSON with the following input data:

PRINTS:
